In statistics, the Kolmogorov-Smirnov test (K-S test or KS test) is a nonparametric test of the equality of continuous (or discontinuous, see Section 2.2), one-dimensional probability distributions that can be used to compare a sample with a reference probability distribution (one-sample K-S test), or to compare two samples (two-sample K-S test).

Kolmogorov-Smirnov test - Wikipedia

For avoiding confusion, there's 2 Kolmogorov-Smirnov tests: there's the one sample Kolmogorov-Smirnov test for testing if a variable follows a given distribution in a population. This " given distribution " is usually -not always- the normal distribution, hence " Kolmogorov-Smirnov normality test ". there's also the (much less common) independent samples Kolmogorov-Smirnov test for testing if a variable has identical distributions in 2 populations.

SPSS Kolmogorov-Smirnov Test for Normality - The Ultimate ...

The Kolmogorov-Smirnov test (Chakravart, Laha, and Roy, 1967) is used to decide if a sample comes from a population with a specific distribution. The Kolmogorov-Smirnov (K-S) test is based on the empirical distribution function (ECDF). Given N ordered data points Y1, Y2, ..., YN, the ECDF is defined as.

1.3.5.16. Kolmogorov-Smirnov Goodness-of-Fit Test

In truth, the Kolmogorov-Smirnov test requires the samples to be taken from a continuous distribution, so discrete data like characters and strings are cute to consider but invalid test data. Still being strict, this test condition also does not hold for integer data unless some hands are waved about the integer data being embedded into real numbers and a distribution cooked up from the probability weights.

The Kolmogorov-Smirnov Test — Kolmogorov-Smirnov

The non-parametric Kolmogorov-Smirnov (KS) test, first recommended for flow cytometry by Young (Young, 1977), is commonly made available with many flow cytometric data analysis programs but the test is rarely used in practice possibly because it tends to be too " sensitive " in the data rich flow cytometry environment, i.e., with flow cytometric data, the KS test reports a significant difference between histograms, even when they are derived from two successive runs of the same sample tube.

Evaluation of an alternative to the Kolmogorov-Smirnov ...

BACKGROUND: The Kolmogorov-Smirnov test is a valid statistical test for comparing distributions that has been recommended for flow cytometric histogram analysis. However, this test is frequently found to be too sensitive for flow cytometric histogram comparisons.

The Kolmogorov-Smirnov (KS) test is used in over 500 refereed papers each year in the astronomical literature. It is a nonparametric hypothesis test that measures the probability that a chosen univariate dataset is drawn from the same parent population as a second dataset (the two-sample KS test) or a continuous model (the one-sample KS test).

the Kolmogorov-Smirnov test is that the distribution of this supremum does not depend on the " unknown " distribution P of the sample, if P is continuous distribution. Theorem 1. The Kolmogorov-Smirnov Test is a type of non-parametric test of the equality of discontinuous and continuous of a 1D probability distribution that is used to compare the sample with the reference probability test (known as one-sample K-S Test) or among two samples (known as two-sample K-S test). A K-S Test quantifies a distance between the cumulative distribution function of the given ...

The above table presents the results from two well-known tests of normality, namely the Kolmogorov-Smirnov Test and the Shapiro-Wilk Test. The Shapiro-Wilk Test is more appropriate for small sample sizes (< 50 samples), but can also handle sample sizes as large as 2000. For this reason, we will use the Shapiro-Wilk test as our numerical means ...

Unfortunately, the one-sample Kolmogorov-Smirnov test is commonly misused to test normality when the parameters of the normal distribution are estimated from the sample rather than specified a priori. The result is that the test is far too conservative, and distributions that are clearly not normal are wrongly classified as such.

Performance evaluation criteria, such as the misclassification rate, the receiver operating characteristics (ROC) curve, the Kolmogorov-Smirnov (KS) statistic and Gini coefficient, are used in credit scoring applications. The KS criterion is very popular in practice (Hand, 2005, Anderson and Hardin, 2009).

The Kolmogorov-Smirnov test procedure involves the comparison between the experimental cumulative frequency and an assumed theoretical distribution function. If the discrepancy is large compared to what is normally expected from a given sample size, the theoretical model is rejected.

The Kolmogorov-Smirnov (KS) test is a statistical procedure for comparing the distribution of random samples. The one-sample KS test can be used to determine whether a data set follows any hypothesized (but fully specified) continuous density.

In this context, Kolmogorov-Smirnov Analysis (KSA) and Partial Kolmogorov-Smirnov analysis (PKS) were proposed respectively. Although both KSA and PKS are based on Kolmogorov-Smirnov (KS) test, they really differ a lot from each other in terms of construction strategies.
